The Global CROCI Book 2026

30 Years of CROCI

Research-Led. Model-Driven.
Market-Relevant.

Marketing Material.

Not for distribution into the USA.

Switzerland: For Qualified Investors (Art. 10 Para. 3 of the Swiss Federal Collective Investment Schemes Act (CISA)).

EMEA: For Professional Clients MiFID Directive 2014/65/EU Annex II) only. No distribution to private/retail investors.

In MENA for professional Clients. Further distribution of this material is strictly prohibited. For business customers only

In APAC and LATAM: For Institutional Investors only. Further distribution of this material is strictly prohibited

Australia/New Zealand: For Wholesale Investors only.

This document does not constitute investment advice nor stock recommendation.

DWS

This book has been produced by the CROCI team of DWS and represents the views of only the CROCI team. It does not constitute investment advice, investment recommendation or independent research. The CROCI team bases its views on the application of the CROCI valuation methodology as well as its own views on the financial markets. The CROCI team does not manage client portfolios.

Marketing Material.

For MiFID Professional Investors only and not for retail distribution. For institutional investors only. For business customers. Not for distribution into the USA.

Switzerland: For Qualified Investors (Art. 10 Para. 3 of the Swiss Federal Collective Investment Schemes Act (CISA)). EMEA: For Professional Clients (MiFID Directive 2014/65/EU Annex II) only.

No distribution to private/retail investors. In APAC and LATAM: For Institutional Investors only. For South Korea: This material has been provided upon your specific request on a reverse solicitation basis.

Singapore and Hong Kong: This material is provided to Addressee Only who are Professional / Accredited Investors in Hong Kong / Singapore respectively (or equivalent classification in other jurisdiction).

Important Information:

This book is intended for Professional Investors only who understand the strategies and views introduced in this book and can form an independent view of them. CROCI represents one of many possible ways to analyse and value stocks. Potential investors must form their own view of the CROCI methodology and evaluate whether CROCI and investments associated with CROCI are appropriate for them.

Past performance is not an indicator of future performance, and any forecast or projection may not be realised. Any current or past company metrics may not be indicative of future metrics. Any investment in equities can go down as well as up and investor capital may be at risk up to a total loss.

In the data and charts presented throughout this book, “E” refers to financial years that are not yet reported. Forecasts of accounting data for these years are derived from market’s consensus estimates as reported by LSEG. CROCI metrics for the forecast years are calculated by applying CROCI model to these consensus estimates. These forecasts might prove to be inaccurate or incorrect. The CROCI team does not make any forecasts or projections of accounting data. Data for historical years are derived from company reports and other publicly available sources.

In the tables, Summary of Profitability and Growth: Non-Financials and Financials, ↑↓ indicates the upward and downward change compared to the previous year.

Please refer to the important information at the end of this book.

An introduction to the Cash Return on Capital Invested (CROCI) Analysis

A Metric Renaissance

With time, everyday objects, habits, or words develop a life of their own, and we quickly forget their original meaning, provenance, or use. Have you ever wondered why Cinderella wears glass shoes, for example? In an early version of Charles Perrault's story, her shoes were made of *vair*, an archaic French word for squirrel fur, which subsequently morphed into *verre*, glass. Similarly, P/Es have lived a life of their own since they were made popular in the 1950s and 1960s. Today, they are often thought of as "a ratio that tells you whether a stock is cheap or expensive". Few of us use them for what they really are: short-hand for the ratio of price-to-book and return on equity (RoE)—and the inverse of the cost of capital. Yet every time we use a P/E ratio, we implicitly take a view on both.

The Value/Return dilemma

Any work on valuation involves the comparison of a return metric with a value metric in the context of an ambient cost of capital (COC) and given a growth rate. In other words, investors want to know what they are getting (return) for what they are paying (value), and how that compares with alternative investments (COC). The problem with conventional price-to-book and RoE—and therefore with P/Es—is that the inputs to this set of metrics are designed by accountants, whose business it is not to get to the economic value of assets. Therefore, we view them as inappropriate for financial analysis.

Yes, of course, there is a correlation (+) between P/Bk and RoE. The slope exists, but the correlation shows an R^2 of only about 0.6 or less, and we believe the relationship is not statistically significant enough for systematic use or reliability of the conventional price/earnings (P/E) model.

Yet accountants, for all their sins, have a substantial advantage over the outside-in financial analyst: they are privy to virtually every piece of information within the company. Departing from their metrics to get to the true economic value of assets forces financial analysts to take the risk of estimating such essential items as economic lives of assets or amount of goodwill written off reserves. This is why, in our opinion, more advanced combinations of value and return metrics have not been widely used until recently, despite the fact that the complete theoretical background to asset valuation was finalised half a century ago.

We believe there are three reasons why this has changed now. One, the business of investing is now a global business, and analysts need to compare thousands of returns, lives or operating costs across the world. This enhances their ability to estimate the right numbers for a particular company because it widens the universe of comparables. Two, the world has become more capitalist, and shareholders are demanding more information from management, while punishing companies with obscure or misleading accounting standards by lowering their share prices. Three, the processing power of computers and internet technology both enable data analysis to an extent that was not even dreamt even in the early 1990s. The collapse of the Technology bubble in 2000, followed by the financial crisis of 2008 has forced equity investors to focus more on the Value / Return dilemma. Of course, this does not automatically solve the problem of measuring it accurately.

What CROCI is

The CROCI system was created with the sole goal of improving stock picking and portfolio management. The number of new theories is kept to a minimum (we have nothing to add to Adam Smith and Miller Modigliani anyway) and pragmatism is always preferred. We think that investors should keep things as simple as possible and think about equity valuation in the following manner:

P/Es are the most simplified version of the value/return dilemma, another way of expressing price-to-book and return on equity. As such, P/Es are speaking the same language as the shareholder value proponents, the language of cost of capital, returns and valuations of capital invested. But they do so in an ambiguous way, in as much as the metric used is simplified in the extreme - based on reported accounts - and implicit.

Price to Book and Return on Equity work well in a world where financial gearing does not exist, where there is one single accounting standard, where goodwill is not written off against reserves, where it is appropriate to depreciate assets in a linear way, where no asset revaluation occurs, where intangible assets are immaterial and where there is no inflation.

Since the world is not quite like this, CROCI analysts have to make a number of adjustments to the original value/return metric, in order to transform it from an **accounting** to an **economic metric**. This is the essence of CROCI. Just how many adjustments will depend on the company itself, of course—some companies need a great deal of standardization and subsequent economic adjustments, others very little. We have identified five essential adjustments that transform price-to-book into Enterprise Value-to-Net Capital Invested (EV/NCI) and return on equity into Cash Return On Capital Invested (CROCI). Dividing the first by the second still yields a 'P/E' ratio, but with an explanatory power that has moved from an R^2 of around 0.6 to one of around 0.8, giving investors a meaningful chance of making money. We call it '**Economic P/E**', because it takes into account the full economic capital used by companies and is calculated with a return ('CROCI') that does not depend on reported earnings.

Not a new cash flow metric, but a way of making existing ones work

It has long been understood that, as a basis for valuation, reported earnings work at best on average. As a result, conventional P/Es 'work' in only a certain number of cases. The trouble is that the remaining ones, where price to book and return on equity (the components of the P/E ratio) have a low or non-existent correlation, is often where the most interesting investments can be found—high growth companies, companies with a high content of intangible assets, companies with a very strong competitive advantage etc. An investor can never know for sure whether an investment belongs to the universe where the P/E 'works' or not. That's really why accounting earnings-based valuation work is largely useless, in our view.

Cash-flow-based analysis (free, or gross with an assumption of asset life) tends to have a higher explanatory power for share prices. It is by no means the Holy Grail. It is also possible to manipulate cash flow, but it is significantly less easily done than earnings. Cash flow metrics have been in existence for years. Rather than redesign new ones, investors simply need to start using them.

There is nothing wrong with dividing Price-to-Book by RoE

CROCI (Cash Return on Capital Invested) does not claim any breakthrough in financial theory. It still compares a level of return to an asset multiple. That's because there is nothing wrong in assuming a relationship between a level of return and the price paid for the assets generating that return. In fact, it ought to be obvious that there should be one, and indeed, one that can be measured empirically. What is wrong in our view is to use the book value as a measure of assets and return on equity as a measure of return.

CROCI continues to use returns and asset multiples, but with substantial adjustments. CROCI is a cash return—real (inflation-adjusted) and calculated on full economic capital. We also prefer to calculate gross cash returns with a finite asset life, rather than free cash returns to infinity (the two are mathematically equivalent). This means that we calculate CROCI as an internal rate of return based on our estimate of the economic asset life. We call the asset multiple EV/NCI (enterprise value to net capital invested). NCI includes intangible capital such as R&D and advertising as well as leased assets. It aims to capture the full economic capital used by a company (hence 'economic capital'), as opposed to some residual value determined by accountants (the 'book value'). But if you divide EV/NCI by CROCI, you still find a P/E ratio. However, it is based on real, economic data, and is therefore more likely to be meaningful than a conventional reported P/E.

The real insight is in the market expectations, not the forecasts.

However, a clean set of returns (CROCI) and asset multiples (EV/NCI) is just a pre-requisite. We use these to calculate economic profits (EP), a distant relative of EVA. Our belief is that there is significant insight to be gained in comparing actual EP (which is CROCI minus the cost of capital times real net assets, or NCI) with market expectations. The latter can be calculated with a minimum of financial engineering. Because NCI is the real economic replacement value of net assets, the asset multiple (EV/NCI) is akin to a Tobin's Q ratio. But, unlike the original Q ratio, it includes capitalised

intangibles. Therefore, any ratio other than 1 indicates expected value creation or destruction. If investors were discounting future CROCI to be at the cost of capital exactly, they would pay no more than the replacement cost of assets, ie, the value of NCI exactly. The difference between EV and NCI is therefore equivalent to the net present value of all future EP discounted by the market. Multiply this by the cost of capital and you have the average EP discounted by the market, which can then be compared to the actual, forecast or historical EP, as desired. Since 1996 we have built up a substantial body of evidence that there is financial merit in comparing market expectations of EP with actual EP. This is substantially similar to comparing market-implied cash returns (dependent on the economic price-to-book) with achieved or forecast returns.

CROCI cum and ex Goodwill / Implied CROCI

CROCI® is the real post-tax return on total capital invested in the company. The solid bars in the chart above show our core measure of CROCI when we exclude goodwill¹ from the capital base.

The split in the bar shows the level of CROCI that the company would generate if we included goodwill as part of the capital base.

The dotted line reflects our market implied cost of capital. If CROCI exceeds this level, the company is value creative.

The diamond shown next to the forecast period reflects the level of CROCI that the market currently implies is sustainable, calculated as $EV/NCI \times COC$.

Use this chart to assess:

- whether returns are growing or fading. (Excess returns are a measure of competitive advantage, giving information about the company's competitive position.)
- the volatility and cyclical nature of the business
- whether the company creates or destroys value
- the impact of acquisitions on CROCI

In this example, Coca Cola has shown stable and high levels of returns over the very long term, exceeding the cost of capital (dotted line) on average by 2.8x. Goodwill had a limited impact on returns up to 2005. The market implies a premium of 500bps over current level of CROCI for 2026E

Net Capital Invested (NCI)

Net Capital Invested reflects our estimate of the level of economic assets invested in the business in today's money after taking into consideration inflation, and capitalisation of intangibles.

The chart shows the dynamics of growth in real assets. Each annual bar shows the absolute value of the Net Capital Invested (NCI) excluding goodwill in blue. The amount of goodwill accumulated historically is indicated in grey.

The line shows the year-on-year change in the NCI and its trend over time can be seen as an indicating of the growth rate of the business.

Use this chart to assess:

- the nature of the growth in capital
- the level of organic growth in capital

In this example, Coca Cola has shown strong growth till 2011, mostly organic, with limited contribution from acquisitions. Since then, NCI is stable with minimal growth expected by the consensus in 2026E

Economic Earnings & Implied Economic Earnings

Economic Earnings show, in today's money, the absolute level of economic return generated each year, calculated as $CROCI \times \text{Net Capital Invested}$, the two charts to the left.

Implied Economic Earnings is calculated as the implied CROCI (see left) multiplied by the Net Capital Invested. Economic Earnings and implied Economic Earnings are shown excluding the effect of goodwill.

Economic Earnings are not impacted by assumptions concerning the cost of capital, although the Implied Economic Earnings are.

Use this chart to assess:

- whether the company has generated, in real terms, growth in Economic Earnings
- the level of Economic Earnings that the market presently discounts as sustainable.

In this example, strong NCI growth and a stable return profile allowed Economic Earnings to compound rapidly till 2011; barely stable since then. The market implies a premium of 1.3x over current levels of earnings for 2026E.

¹ CROCI defines goodwill as the acquisition premium post adjustment for the capitalisation of intangibles

CROCI Drivers

Value / Returns

Economic Profit / Market Implied Economic Profit

The drivers of CROCI returns can be broken down into productivity of the invested capital (defined as Sales to Gross Capital Invested (GCI)) and sales margin (defined as the CROCI cash flow to sales).

The price paid for an asset should be equal to the return of that asset relative to the cost of capital (adjusted for growth).

In CROCI-speak, the economic price to book is called EV/NCI (bars) and we compare this to the CROCI / COC (line).

For each year we show the EV/NCI using the high, low and average share price for the year to allow an historical valuation range to be determined.

The diamond is today's EV/NCI and allows comparison with historic valuation and current return generation

Economic Profits (bars) represent Economic Earnings after paying for the cost of capital and is defined as excess returns times operating assets (i.e. (CROCI – COC) x NCI) and can be seen as the 'value added' each year.

Implied Economic Profit (line) shows the average annual economic profits discounted by the market in each year, $(EV - NCI) \times COC$.

If the Implied Economic Profit (line) exceeds the Economic Profit (bar), the market is discounting growth in EP.

Use this chart to assess whether:

- the improvement in CROCI has been driven by improving margins and/or by improving asset productivity (or the converse)
- the trend that has driven any change in returns so far is losing/gaining momentum

Use this chart to assess:

- the trend level of CROCI/COC over the cycle
- the premium/discount of EV/NCI vs CROCI/COC over time
- where the current EV/NCI is, relative to its own past range as well as the trend developing in CROCI/COC, i.e. if the market is pricing a structural change in relative return

Use this chart to:

- assess the absolute level of value creation over time
- compare the level of value creation that the market is discounting today with historical levels

In this example, there has been remarkable consistency in both drivers over time, with structural change in 2000, 2011 and 2017. However, the CROCI return remained stable over the period barring 2020.

In this example, the market afforded the company a significant growth premium between 1994 and 2004. Between 2005 and 2010, EV/NCI has moved in line with CROCI/COC suggesting no significant growth premium is valued by the market, which has again marginally reversed from 2011 onwards. Currently EV/NCI is 5.0x compared to 3.8x of CROCI/COC

In this example, the economic profit did indeed grow between 1994 and 2004 but never reached the level implied by the market. Between 2005 and 2010, market implied level has moved in line with economic profit suggesting no growth premium, which reversed again from 2011. Currently, the market expects that economic profit creation will be higher (highest since 1998) than the level expected by the consensus in 2026E-27E.

	The Internal Rate of Return (IRR) equalizing the economic Gross Capital Invested (GCI) with cash flows, over the economic life of assets				Economic price multiple, calculated as EV/NCI divided by CROCI				Share price divided by adjusted earnings per share				Market-implied cost of capital (CoC), equating the global aggregate EV with projected value creation

Our estimates of the weighted average life of assets and their age

Accounting life is calculated, by dividing reported depreciable gross assets by the current depreciation charge. Age is calculated as reported accumulated depreciation divided by current depreciation charge

Level of CROCI that the market implies is sustainable, calculated as EV/NCI x CoC.

Estimated replacement value of the economic assets base, comprising the inflation adj tangible assets, capitalized intangible assets, lease and NWC

Economic earnings is the absolute level of economic return generated each year, calculated as CROCI x NCI. Market Implied economic earnings is the level of return expected by the market, calculated as implied CROCI multiplied by NCI

Introduction to CROCI Approach for Banks

CROCI is essentially a valuation approach based on the due diligence of company accounts. An understanding of risks and sources of return is necessary for us to add a company to CROCI coverage. So, whilst we have been analysing the accounts of financial companies since 2007, uncertainties around the structural and regulatory changes to the industry and their reflection of its economic reality earlier prevented their inclusion in our full investible coverage.

The tightening of regulation following the financial crisis, however, has helped to clarify the financial statements of US banks. New standards have curtailed management's free rein to determine asset risk profiles and levels of required capital have increased. Some jurisdictions, e.g. Australia, even have regulations tougher than international standards.

The move to the expected credit loss model, regular stress testing, higher capital requirements for systemically important banks, etc. have been crucial in strengthening the banking system. However, in the U.S. there has been some loosening of regulatory standards for smaller banks in the past few years. The option given to smaller banks to ignore accumulated other comprehensive income (AOCI), especially unrealized losses on their bond portfolios, in capital calculations was among the main causes of crisis in U.S. regional banking space in 2023.

A sudden increase in the Fed's policy rate led to large losses unrealized in these banks' bond portfolios but as depositors started looking for higher yields elsewhere, a sale of these bonds to handle deposit pressure resulted in losses being realized and capital being wiped-off. CROCI, however, does not give any bank the option to ignore AOCI and hence our estimated CET1 capital levels indicate this risk clearly. The episode also highlights the importance of harmonizing global capital calculations while evaluating the risks of the banking sector.

CROCI and Banks

It is often assumed that banks are too difficult to do on CROCI, or that the CROCI model doesn't work for banks. Neither is really true. Banks are in many ways easier to analyse than non-financial companies. The asset side of their

balance sheet is composed of monetary assets which do not need complex inflation adjustment, or the capitalization of intangible assets. In fact, the model "works" just as well for banks as it does for any other operating asset.

The difficulty, however, is the calculation of the relevant market value. An enterprise value that included all debt would be of limited interest, considering that a bank's balance sheet can be leveraged up to 12x, against 1x on average for non-financial companies. As a result, the slightest error in the assessment of banks' total liabilities would have disproportionate consequences for the conclusions on valuation. It is much more appropriate for a banks model to be expressed in terms of equity and net assets. So the traditional price to book and RoE approach—in other words the normal PE ratio—is more meaningful for a bank than for a non-financial company.

The non-applicability of the industrials approach

CROCI challenges traditional accounting conventions and lays great emphasis on cash-flow-based analysis. For banks, this is not very relevant because, for them, cash is an operating asset. Similarly, 'borrowing and lending' is tantamount to 'manufacturing and selling' at non-financial companies. Further, Fixed Assets represent only 1% (see table on Page 1041) of a bank's total assets; consequently, depreciation policies have very little impact on bank profitability.

Banks are highly regulated entities and their leverage levels, though much higher than non-financials, are restricted by regulations. These regulations vary across jurisdictions. Hence, bringing banks to a common standard and determining their genuine capital-adjusted performance requires a different approach.

Banks bear a higher cost of capital than non-financials

Using a traditional price-to-book and RoE approach is severely flawed if investors want to know whether BNP Paribas is better value than Saint-Gobain, or if Wells Fargo is more expensive than Coca-Cola. This may not be of huge interest for those who want to keep a small tracking error, for investors who are benchmark huggers. But for value investors who seek diversification and want

to position their portfolio where value is, irrespective of market cap weights, the PE ratio is of much less use.

The reason is that the level of the PE gives an idea of value (an imperfect one with accounting data, but an idea nonetheless) and a measure of expected return, i.e. of risk premium. Banks are on a lower PE ratio than non-financial companies, on average, not because they are better value in an absolute sense, but because they are more risky, i.e. priced with a higher risk premium than the rest of the market. In this respect, it makes little sense that index providers fill up their value indices with bank shares (with a weight of typically more than 30%), without adjusting for their higher risk. Their low multiple is treated as offering value without compensating for the increased risk.

Need for Continued Evolution of Banks Model

The banking sector is heavily regulated and strongly correlated with the economy, so tends to witness regular intervention by regulatory authorities. A non-financial company can certainly expect changes to its business environment over the cycle, but a bank can be subjected to a whole raft of regulations.

The Basel rules are a good illustration of this. Basel I was criticized for being less sensitive to the risks faced by banks. This led to Basel II, which allowed banks to use their own internal ratings-based models. However, regulators realized that capital requirements calculated using internal models were lower than those given by standardized models in a large majority of cases. As a consequence, the Basel committee is now proposing regulations that would restrict the use of internal models. Thus, regulations seem to have come full circle. Long-term investors need to account for the fact that bank regulations are rarely static and can be cyclical, just like business cycles.

Also, regulations vary across jurisdictions and, despite concerted efforts by authorities to harmonise them, it is unlikely that these variations will converge any time soon. A case in point is capital floors—in Europe, some countries strongly oppose their introduction whereas the US is in favour of them. Since regional differences are a consequence of differences in economic, monetary and credit cycles, these factors are unlikely to go away.

In the end, value investors need to continuously monitor and account for these variations in their analysis of the sector. This is in keeping with our differentiated CROCI approach for analyzing banks, in which we meticulously revise our models to adjust for national variations whilst also ensuring that valuations reflect economic reality as far as possible.

Inflation Adj. ROC cum & ex Goodwill & Implied ROC

For Banks, our traditional CROCI® metric is called Inflation Adjusted Return on Capital (ROC), a measure of earnings calculated upon Adjusted Tier 1 capital. The solid bars in the chart above represents ROC.

The split in the bar shows the level of ROC that the bank would generate if we included goodwill as part of the Adjuster Tier 1 capital.

The dotted line reflects our market implied cost of capital for banks. If Inflation adj. ROC exceeds this level, the company is value creative.

The diamond shown next to the forecast period reflects the level of ROC that the market currently implies is sustainable, calculated as EV/Adjusted Tier 1 capital x COC.

Use this chart to assess:

- whether returns are growing or fading
- the volatility and cyclical nature of the business
- whether the company creates or destroys value

In this example, the excess profits of Wells Fargo over the decade preceding the financial crisis have been fading away due to rising capital requirements.

Higher capital inherently reduces the risk but has also reduced the return, as evident from average ROC of 25% pre-financial crisis compared to average ROC of 11% after the crisis.

Adj. Tier 1 capital *

Adjusted (Adj.) Tier 1 capital is the Tier 1 capital reported by the bank normalized for differences across different regulators. The chart shows the dynamics of growth in Adj. Tier 1 capital.

Each annual bar shows the absolute value of the Adj. Tier 1 capital in blue. The amount of goodwill accumulated historically is indicated in grey.

The line shows the year-on-year change in the Adj. Tier 1 capital.

Use this chart to assess:

- the level of growth in loss absorbing capacity of a bank, i.e. the capital level

Wells Fargo's capital has increased post financial crisis, due to the regulatory changes that increased the minimum capital ratios to be maintained by a bank.

RWA * and Tier 1 Ratio

Risk-weighted assets (RWAs) are banks assets and off-balance sheet exposures weighted according to risk. Tier 1 ratio is calculated as Adj. Tier 1 capital/RWAs. Each annual bar shows the absolute value of the RWAs in blue and the line shows Tier 1 ratio.

Use this chart to assess:

- Change in RWA which denotes the trend of risk.
- Capital strength of the bank in terms of Tier 1 ratio.

There has been a continuous increase in Wells Fargo's Tier1 ratio post financial crisis. RWAs increased in 2013 as an impact of Basel III implementation and is at the same levels until 2016, then gradually declining over the years mainly due to muted business growth.

Return Drivers

The two main operating drivers of Return on capital for Banks are Pre-Provision Earnings and Provision for Loan Losses. Profitability of the business and credit quality of assets, both are cyclical and are driven by economic growth, level of interest rates, credit cycles etc. The solid line shows pre-provision profits, and the dotted line denotes provision for loan losses, both measured as a percentage of RWAs.

Use this chart to assess whether:

- the improvement in ROC has been driven by improving pre-provision profits and/or by improving credit quality of assets
- the drivers of ROC are trending higher or lower, i.e. if pre-provision profits and / or provision for loan losses are growing or coming down relative to RWA

In this example, both the drivers of Wells Fargo's ROC were favourable for the bank's profitability before the crisis, i.e. provisions were low and pre-provision profit was high.

However, during the financial crisis, this situation got reversed and the two drivers demonstrate unfavourable business conditions as well as increased credit losses.

Value & Returns ex Goodwill

The price paid for an asset should be equal to the return of that asset relative to the cost of capital.

The economic price to book is called EV/Adj. Tier 1 capital (bars) and we compare this to the ROC / COC (line).

For each year we show the EV/Adj. Tier 1 capital using the high, low and average share price for the year to allow an historical valuation range to be determined.

The diamond is today's EV/Adj. Tier 1 capital and allows comparison with historic valuation and current return generation.

Use this chart to assess:

- the premium/discount of EV/Adj. Tier 1 capital vs ROC/COC over time
- where the current EV/Adj. Tier 1 capital is, relative to its own past range as well as the trend developing in ROC/COC, i.e. if the market is pricing a structural change in relative return

There is closer co-relation between price to book and ROC/COC of Wells Fargo. Post crisis, a lower return translated into a lower price to book. As a result, price to book multiple of Wells Fargo that averaged around 3.4x pre financial crisis, is currently at 1.6x.

Economic Profit & Market Implied EP ex Goodwill

Economic Profits (EP) (bars) represent Economic Earnings after paying for the cost of capital and is defined as excess returns times capital (i.e. $(ROC - COC) \times \text{Adj. Tier 1 capital}$) and can be seen as the 'value added' each year.

Implied Economic Profit (line) shows the average annual economic profits discounted by the market in each year, $(EV - \text{Adj. Tier 1 capital}) \times COC$.

If the Implied Economic Profit (line) exceeds the Economic Profit (bar), the market is pricing growth in EP.

Use this chart to:

- assess the absolute level of value creation over time
- compare the level of value creation that the market is pricing today with historical levels

Wells Fargo's economic profit did grow between 1995 and 2014 (except for 2008 which was the year of financial crisis), in line with market implied EP. Economic profit is in a declining trend after 2014 mainly due to lack of revenue growth. Rising interest rates post pandemic, and growth in fee income have aided the recovery of economic profit in recent years.

Source: DWS CROCI Database, as at 17 June 2026. The CROCI database is created from historical data which is derived from company sources, Bloomberg and Factset consensus analyst forecasts, and DWS estimates.

Reported Earnings as adjusted for EV definition, Exceptionals and implied inflation charge.

In order to make the valuation comparable with Non-Financials, Bank's P/E ratio is adjusted by the ratio of COC of financials (5.8%) to that of non-financial companies (4.2%)

Market-Implied cost of capital, structurally higher than that of non-financial companies. It represents the premium that investors demand for accepting higher risk, principally in the form of higher leverage

Level of ROC that the market implies is sustainable, calculated as EV/Adjusted Tier 1 capital x COC

Introduction to CROCI

An Introduction to the Cash Return on Capital Invested (CROCI) Analysis

A Metric Renaissance

With time, everyday objects, habits or words develop a life of their own, and we quickly forget their original meaning, provenance or use. Have you ever wondered why Cinderella wears glass shoes, for example? In an early version of Charles Perrault's story, her shoes were made of *vair*, an archaic French word for squirrel fur, which subsequently morphed into *verre*, glass. Similarly, P/Es have lived a life of their own since they were made popular in the 1950s and 1960s. Today, they are often thought of as "a ratio that tells you whether a stock is cheap or expensive". Few of us use them for what they really are: short-hand for the ratio of price-to-book and ROE—and the inverse of the cost of capital. Yet every time we use a P/E ratio, we implicitly take a view on both.

The Value/Return dilemma

Any work on valuation involves the comparison of a return metric with a value metric in the context of an ambient cost of capital (CoC) and given a growth rate. In other words, investors want to know what they are getting (return) for what they are paying (value), and how that compares with alternative investments (CoC). The problem with conventional price-to-book and ROE—and therefore with P/Es—is that the inputs to this set of metrics are designed by accountants, whose business it is not to get to the economic value of assets. Therefore, we view them as inappropriate for financial analysis.

Yes, of course, there is a correlation (+) between P/Bk and RoE. The slope exists, but the correlation shows an R^2 of only about 0.6 or less, and we believe the relationship is not statistically significant enough for systematic use or reliability of the conventional PE model.

Yet accountants, for all their sins, have a substantial advantage over the outside-in financial analyst: they are privy to virtually every piece of information within the company. Departing from their metrics to get to the true economic value of assets forces financial analysts to take the risk of estimating such essential items as economic lives of assets or amount of goodwill written off reserves. This is why, in our opinion, more advanced combinations of value and return metrics have not been widely used until recently, despite *the fact that the complete theoretical background to asset valuation was finalized half a century ago.*

We believe there are three reasons why this has changed now. One, the business of investing is now a global business, and analysts need to compare thousands of returns, lives or operating costs across the world. This enhances their ability to estimate the right numbers for a particular company because it widens the universe of comparables. Two, the world has become more capitalist, and shareholders are demanding more information from management, while punishing companies with obscure or misleading accounting standards by lowering their share prices. Three, the processing power of computers and internet technology both enable data analysis to an extent that was not even dreamt even in the early 1990s. The collapse of the Technology bubble in 2000, followed by the financial crisis of 2008 has forced equity investors to focus more on the Value / Return dilemma. Of course, this does not automatically solve the problem of measuring it accurately.

What CROCI is

The CROCI system was created with the sole goal of improving stock picking and portfolio management. The number of new theories is kept to a minimum (we have nothing to add to Adam Smith and Miller Modigliani anyway) and pragmatism is always preferred. We think that investors should keep things as simple as possible and think about equity valuation in the following manner:

P/Es are the most simplified version of the value/return dilemma, another way of expressing price-to-book and return on equity. As such, P/Es are speaking the same language as the shareholder value proponents, the language of cost of capital, returns and valuations of capital invested. But they do so in an ambiguous way, in as much as the metric used is simplified in the extreme - based on reported accounts - and implicit.

Price to Book and Return on Equity work well in a world where financial gearing does not exist, where there is one single accounting standard, where goodwill is not written off against reserves, where it is appropriate to depreciate assets in a linear way, where no asset revaluation occurs, where intangible assets are immaterial and where there is no inflation.

Since the world is not quite like this, CROCI analysts have to make a number of adjustments to the original value/return metric, in order to transform it from an **accounting** to an **economic metric**. This is the essence of CROCI. Just how

many adjustments will depend on the company itself, of course—some companies need a great deal of standardization and subsequent economic adjustments, others very little. *We have identified five essential adjustments that transform price-to-book into Enterprise Value-to-Net Capital Invested (EV/NCI), and return on equity into Cash Return On Capital Invested (CROCI).* Dividing the first by the second still yields a 'P/E' ratio, but with an explanatory power that has moved from an R^2 of around 0.6 to one of around 0.8, giving investors a meaningful chance of making money. We call it '**Economic P/E**', because it takes into account the full economic capital used by companies and is calculated with a return ('CROCI') that does not depend on reported earnings.

Not a new cash flow metric, but a way of making existing ones work

It has long been understood that, as a basis for valuation, reported earnings work at best on average. As a result, conventional P/Es 'work' in only a certain number of cases. The trouble is that the remaining ones, where price to book and return on equity (the components of the P/E ratio) have a low or non-existent correlation, is often where the most interesting investments can be found—high growth companies, companies with a high content of intangible assets, companies with a very strong competitive advantage etc. An investor can never know for sure whether an investment belongs to the universe where the P/E 'works' or not. That's why accounting earnings-based valuation work is largely useless, in our view.

Cash-flow-based analysis (free, or gross with an assumption of asset life) tends to have a higher explanatory power for share prices. It is by no means the Holy Grail. It is also possible to manipulate cash flow, but it is significantly less easily done than earnings. Cash flow metrics have been in existence for years. Rather than redesign new ones, investors simply need to start using them.

There is nothing wrong with dividing Price-to-Book by RoE

CROCI (Cash Return on Capital Invested) does not claim any breakthrough in financial theory. It still compares a level of return to an asset multiple. That's because there is nothing wrong in assuming a relationship between a level of return and the price paid for the assets generating that return. In fact, it ought to be obvious that there should be one, and indeed, one that can be measured empirically. What is wrong in our view is to use the book value as a measure of assets, and return on equity as a measure of return.

CROCI continues to use returns and asset multiples, but with substantial adjustments. CROCI is a cash return—real (inflation-adjusted), and calculated on full economic capital. We also prefer to calculate gross cash returns with a finite asset life, rather than free cash returns to infinity (the two are mathematically equivalent). This means that we calculate CROCI as an internal rate of return based on our estimate of the economic asset life. We call the asset multiple EV/NCI (enterprise value to net capital invested). NCI includes intangible capital such as R&D and advertising as well as leased assets. It aims to capture the full economic capital used by a company (hence 'economic capital'), as opposed to some residual value determined by accountants (the 'book value'). But if you divide EV/NCI by CROCI, you still find a P/E ratio. However, it is based on real, economic data, and is therefore more likely to be meaningful than a conventional reported P/E.

The real insight is in the market expectations, not the forecasts.

However, a clean set of returns (CROCI) and asset multiples (EV/NCI) is just a pre-requisite. We use these to calculate economic profits (EP), a distant relative of EVA. Our belief is that there is significant insight to be gained in comparing actual EP (which is CROCI minus the cost of capital times real net assets, or NCI) with market expectations. The latter can be calculated with a minimum of financial engineering. Because NCI is the real economic replacement value of net assets, the asset multiple (EV/NCI) is akin to a Tobin's Q ratio. But, unlike the original Q ratio, it includes capitalised intangibles. Therefore, any ratio other than 1 indicates expected value creation or destruction. If investors were discounting future CROCI to be at the cost of capital exactly, they would pay no more than the replacement cost of assets, ie, the value of NCI exactly. The difference between EV and NCI is therefore equivalent to the net present value of all future EP discounted by the market. Multiply this by the cost of capital and you have the average EP discounted by the market, which can then be compared to the actual, forecast or historical EP, as desired. Since 1996 we have built up a substantial body of evidence that there is financial merit in comparing market expectations of EP (DEP) with actual EP. This is substantially similar to comparing market-implied cash returns (dependent on the economic price-to-book) with achieved or forecast returns.

Why are Returns on Equity and Price-to-Book Insufficient?

The low explanatory power of price-to-book and ROE (aka: 'the P/E ratio') is not evenly distributed. The relationship tends to work well for 'simple' companies and break down for more 'complex' ones. Unfortunately, the latter frequently offer the highest potential for de-rating or re-rating, and hence are the most 'interesting' companies from the point of view of an equity investor. The limits of the P/E ratio come from two sources: the way accountants disagree on asset lives, and the fact that equity, or book, does not represent a genuine economic entity.

Accountants Disagree on Asset Lives

The price of a business can be described very simplistically as the market value of its assets after taking into consideration their obsolescence—in other words after depreciation. Put in these terms, the rate at which these assets get depreciated becomes pretty crucial in the valuation process. Across the world, accounting standards vary substantially, and accountants, inspired by local tax authorities, take different views on asset lives, and therefore depreciation. In the UK, where accounting standards tend to be less conservative than, say, in Germany, asset lives are on average longer than on the Continent. An obvious example of this is the depreciation of airplanes by IAG (formerly British Airways) and Deutsche Lufthansa. Reading the report and accounts one sees different asset lives. According to IAG, 'Fleet is generally depreciated over periods ranging from 23 to 31 years after making allowance for 5% residual value'. Compare this to Lufthansa where 'the useful life of Commercial aircraft and reserve engines is twenty years to a residual value of 5 per cent' (the useful life was just twelve years until 2012). These are vast differences! In some cases, it is possible for a UK company to argue that the level of maintenance of its property is high enough to be allowed not to depreciate its buildings. This is the case for a number of pub and hotel owners. Thus in the world of global accounting, "book", "Buch" and "bok" do not necessarily mean the same thing.

Share Price Performance and ROE Not Closely Correlated

ROE performs poorly as a valuation tool. Only by applying some or all of our five essential adjustments can investors hope to read financial data in a meaningful way. We are adamant that these adjustments are not redundant complications. It is inherently complicated to extract true economic data from tangled accounting data and P/E ratios. The CROCI process, however, is designed to simplify financial analysis for investors, by avoiding the implicit shortcuts and mistakes embedded in the ubiquitous P/E ratio.

I. The Five CROCI Adjustments to the Value / Return Matrix

The first three adjustments that we propose to adjust financial statements aim at presenting a fairer account of gross (i.e. pre depreciation) invested capital. Investors might find this starting point surprising, given that financial markets value post- not pre-depreciation assets. Mathematically, there is a cross over between a model of return on asset based on gross assets and one based on net assets¹. In the first instance, the analyst assumes that the assets are consumed through obsolescence. It is a model with a finite asset life and no re-investment. In the second instance, assets live indefinitely thanks to a regular reinvestment.

We prefer to use a model based on gross assets for the very reason that we are distrustful of accounting depreciation (more on this later). The CROCI cash return is therefore the Internal Rate of Return (IRR) equalising the gross economic value of the assets of the company with gross cash flows, over the life of these assets. Schematically, it can be represented as in the following chart.

CROCI – Cash Return on Capital Invested

Once the return on asset (CROCI) is calculated, the asset multiple – the ‘value’ part of the value / return matrix – is of course assessed on the basis of net

assets. Hence our fourth adjustment, depreciation based on economic life of assets. At that stage, investors are equipped with what we believe is a state of the art ‘value’ (EV-to-NCI) / ‘return’ (CROCI) metric. (The relationship between the two is unfortunately not linear whenever the market prices grow.)

1. Adjusting for Financial Gearing

Assets are priced according to the answer to the following question: “At a given level of growth, what economic return do these assets generate, and how does it compare with the cost of allocating capital to these particular assets, in preference to some others (that is, the cost of capital)?”

Consider the following simplified balance sheet.

Simplified Balance Sheet

Net Tangible Assets	100	Net Financial Debt	80
Net Working Capital	30	Equity (“Book” value)	50
Total Assets	130	Total Liabilities	130

Source: Company Data, DWS CROCI. Data as on 17 June 2026.

If assets employed are $100 + 30 = 130$, then the market value of these assets will be the market capitalisation (the market value of the equity) plus the net financial debt. (NB the market value of the debt is approximated by its book value.) This is why our first adjustment is to substitute the company’s enterprise value for the market capitalisation, and the return on capital employed (here, total assets) for return on equity. The original relationship was:

$$\frac{P}{E} = \frac{\text{Price/Book}}{\text{RoE}}$$

And

‘Degearing’ gives us

$$\frac{\text{Enterprise Value/Capital Employed}}{\text{Earnings Before Interest (EBI)/Capital Employed}}$$

Tax Shield on Financial Charges

Valuing companies on enterprise value is equivalent to considering that assets are 100% financed by equity. Yet debt reduces the tax bill through interest charges, which are tax deductible. In order to be consistent, profits (or cash

¹ See Harold Hotelling (1925), A General Mathematical Theory of Depreciation. American Statistical Association pp 340-353

flow) need to be adjusted by the amount of extra tax that the company should have paid had it been debt-free.

2. Adjusting for Invisible Capital

The basic mission of book-keeping is to inform and protect creditors by giving them a conservative view of the value of those assets left in the company. [read: to be sold on their behalf], should the company default. It follows that if accountants are unsure about the value of certain assets and cannot estimate it with accuracy, or if these assets are not fully paid for by the company, they will almost certainly exclude them from the capital base. These considerations are largely (perhaps not entirely) irrelevant to the financial analyst. If some capital is economically employed, it must make up part of the capital base against which profits are assessed.

In many instances, there can be large swaths of invisible capital employed that need to be written back to the balance sheet. Remember, however, that we are only interested in capital that has been paid for by the shareholders.²

Leasing

Operating leases, which were not recorded on company balance sheets, until 2018³, were absent from reported financial statements. Nonetheless, they constitute capital employed and carry significant economic weight. Equally important, these lease obligations generate liabilities that can affect a company's operating performance. Three adjustments need to be made to capture this.

Leased assets have to be added to the capital employed. Their value can be approximated by calculating the net present value of future leased payments, using the cost of capital as the discount rate.

Debt has to increase by the same amount. These two adjustments will affect the CROCI, the enterprise value, and therefore the EV/NCI ratio.

The cash flow needs to be increased by the amount of each corresponding lease payment, if the latter is originally booked as an operating cost. This effectively treats the lease payments as more of a 'capex' item than an expense.

Since 2019, many accounting standards (IFRS, US GAAP) have mandated that companies recognize operating leases on their balance sheets, accounting for both the right-of-use asset and the associated liability. But there are still countries where lease adjustment is not made (ex: Japanese GAAP has mandated adoption of Leasing standard only from fiscal years starting on or after April 1, 2027)

In today's fast developing technology environment, many software and technology companies rent cloud computing and storage capacity from hyperscalers such as AWS and Azure. Unlike owned data centers or on-premise servers, these arrangements do not involve dedicated underlying assets and therefore do not qualify as leases under accounting standards and remain off balance sheet. As a result, companies can appear less asset-intensive and less leveraged, despite having significant non-cancellable contractual commitments that are economically similar to capital investments through leasing. To address this, the CROCI framework treats cloud commitments in a manner consistent with lease obligations.

Capitalized cloud commitments as percentage of Net Capital Invested (NCI) for Snowflake Inc, US cloud native data and AI platform provider - 2025

Source: Company Data, DWS CROCI. Data as on 17 June 2026

² In the case of concessions, for instance, where assets are used by utility companies but not paid for by the shareholders, it is akin to free capital, and should not be taken into account.

³ IFRS 16 and ASC 842 adopted from January 1, 2019 implements these changes for leases. Refer to these standards for more details.

Non-Capitalised Intangibles

Rationale

Consider Light, a world-class pharmaceutical company. Its finance director, Mr Write-off, decides to get rid of all its tangible assets through lease-back. He also decides to keep enough payables to finance his inventories, and sells his receivables to a factoring company, so that net working capital equals zero. He finally halves the size of his R&D department, so that current projects are taken to completion, but no new project is undertaken. Light's R&D pipeline is equally distributed between phase I, II and III, and has an average life of ten years.

This is the balance sheet of Light after these various operations:

Light's Balance Sheet

Net Tangible Assets	0	Net Debt	-100
Net Working Capital	0	Equity	100
Total Assets	0	Total Liabilities	0

Source: DWS CROCI. Data as on 17 June 2026.

Can this peculiar company, with no booked assets, still generate cash flow next year? And in three years? For sure, cash flow, if any, will be small. There will be no depreciation, and profits will be depressed by the cost of leasing all of Light's factories. But remember also that Light is a leading pharmaceutical company, and that it still maintains its existing pipeline of R&D. In other words, it is very unlikely that Light will not generate cash flow (albeit reduced) after Mr Write-off took his decision, because its R&D pipeline is likely to generate sales and therefore cash flow over the next ten years.

Intangible 'costs', such as R&D and marketing costs, are in fact investments, and therefore assets. The fact that accountants cannot value them and therefore ignore them is irrelevant to economic analysis. If intangibles generate cash flow, they must be capitalised to reflect the true economic return of the company.

Methodology

Capitalising intangibles is a simple exercise in principle, as it is nothing but creating a stock of synthetic assets by systematically capitalising an amount of intangible 'cost-investments' over a given economic life. As can be seen in the table below, most sectors use 'invisible capital'. The move towards 'fab-less' production in technology companies shows how important the asset is.

Estimated Economic Life of Intangible Assets

Pharmaceuticals	10 to 15 years
Chemicals	4 to 7 years
Consumer Goods	4 to 15 years
Automotive	5 to 7 years
Engineering	4 to 7 years
Technology	3 to 5 years

Source: DWS CROCI. Data as on 17 June 2026.

Practically, we accumulate intangible costs, as reported by the company, or estimated by us, over their estimated economic lives, and let the replacement cycle, at economic life + 1 year, renew the stock of intangibles, in the same way as new capex would replace an old plant or piece of equipment. To keep consistency between our measure of capital and cash flow, yearly intangible costs are added to the reported cash flow figure. Being now akin to a capex item, intangible costs do not appear in the profit and loss account anymore (the depreciation of the stock of intangible does, however).

3. Adjusting for Inflation

Stock versus Flow

Any return/value analysis deals with two completely different reported items: **a flow**, represented by profits, cash flow, or any measure of the earnings that have gone through the company's bank account during the reporting period (usually 12 months); and **a stock**, or the accumulated assets that the company uses to generate the flow. The stock is the riverbed, and the flow is the water. Without dwelling on geological considerations, it is obvious that both entities have a completely different age. The riverbed is made of layers of sediments that can be thousands of years old, while the water is transitory. Expressed in monetary terms, this age discrepancy will generate distortions if the value of money changes with time, which is the definition of inflation.

Stock and flows are therefore not directly comparable, unless expressed in the same unit. *The stock needs to be adjusted for inflation.*

A Practical Issue: Defining Age and Deflators

For a company in steady state with no investment cycle (implying that the company replaces assets as soon as they become obsolete) and no growth, the average age of its assets should equal half their life. Table below illustrates this point.

Age Calculation for a No Growth Company

Gross Assets	40
Life	4 years
Scrapping	10 (40 * 1/4)
Capex	10
Depreciation	10
Accumulated Depreciation	20 (2.5*3.5yrs)+(2.5*2.5 yrs)+(2.5*1.5 yrs)+(2.5*0.5 yrs)
Net Assets	20
Age	2 years (40 - 20)/10

Source: DWS CROCI. Data as on 17 June 2026.

Since growth in capital invested will reduce the average age of assets, growth-adjusted accumulated depreciation divided by current depreciation is our proxy for average age, provided that the company depreciates assets linearly (see adjustment 4).

We inflate assets according to their average age, normally using the accumulated GDP deflator of the functional currency. There is an implicit assumption in this adjustment that, over time, currencies will adjust according to the Purchasing Power Parity (PPP) theory⁴. Whilst we agree that this is a simplification of a rather thorny economic issue, it remains that even in this simplified version, inflation adjustment is unavoidable to reconcile the two parts of the value / return relationship.

Further Complications

Asset revaluations, most commonly used now around acquisitions, complicate the matter further. It is of course no coincidence that asset revaluations happen in countries where inflation has been historically high. We would be prompt to interpret this as the proof that accounts get substantially distorted by inflation, to such an extent that high-inflation countries feel obliged to book adjustments to comply with the universal accounting principle of fair representation and, more importantly, to prevent inflation distortions giving rise to inequitable distortions to companies' tax liabilities.

We treat a revaluation reserve as a ready-made current cost adjustment and therefore only apply our own deflator to those assets that have not been adjusted.

Is it Worth All the Effort?

Inflation adjustment is no small task and many seasoned explorers of the world of shareholder value world have given up on it, telling companies and investors that, in a world of low inflation, such adjustments are immaterial. We think that they are wrong and are hoping to be more tenacious. Even during a relatively benign period for inflation, cumulative inflation in the US over the past decade comes out at over 20%.

Imagine Clean PLC, a small UK firm created in 2006 with brand new assets. Seven years later, its post-tax return on capital employed is exactly in line with the average: 12.8% for 2012, and 13.2% for 2013. Adjust for inflation, and returns drops to 10.9% in 2012, and 11% in 2013. Consider now a Brazilian steel company in 2010, with 12-year-old assets. The cumulative deflator would start in 1998 and comes out at 220%.

If the cost of capital was 12% at the time, return on historic assets should have been above 26% to generate real value.

⁴ For companies operating from various locations and having several functional currencies, we construct a company-specific geographically weighted deflator.

4. Adjusting Depreciation

Depreciation has, along with inflation, the most viciously distorting influence on the calculation of financial ratios. It will distort the measure of return when calculated from the net assets (which is almost always the case), and of course the asset multiple itself. Accounting lives, from which depreciation charges are calculated, often have little to do with economic lives which are generally much longer. In addition, companies can choose to depreciate assets in various ways, either linearly, or with accelerated depreciation (declining balance method). Unfortunately, none of these methods is meant to measure the economic decay of the assets. This is why we choose to calculate the return (CROCI) on a gross—i.e. pre-depreciation—basis. As we have said previously, though, returns calculated on a gross or a net basis should be the same if the calculation of the depreciation charge is correct.

Economic versus Accounting Lives

Accounting-based lives are easily calculated, by dividing depreciable gross assets by the current depreciation charge. Somewhat counter-intuitively, this method of calculating life gives a better estimate than the lives which give rise to the depreciation charge in the first place! Indeed, for a zero-growth company in a zero-inflation environment, this method gives exactly the right life however quickly assets are written off. Unfortunately, as soon as the asset base grows in nominal terms, the method's accuracy tails off. Our experience nevertheless shows that this ratio is reliable in approximately 70% of the cases. However, it is the variation within a given time which means that often it cannot be used to produce consistent analysis.

The Utilities sector provides good examples of the inability of reported accounts to capture complex economic lives. Take Kansai Electric Power, the Japanese power generation company. The asset breakdown given in the accounts shows very little difference between 1995/96 and 2023/24. However, the accounting depreciation life changes substantially over that time.

In 1995/96, the accounting depreciation life, calculated by dividing gross assets by the depreciation charge is 27 years. It does not take much knowledge of the power generation industry for this to sound like an extremely aggressive depreciation rate. It is perhaps unsurprising that the accounting depreciation life, calculated in the same way (and for similar assets) in 2024/25 rose to 51 years. CROCI estimates a life of around 41 years, based on the effective useful

life observed for the various type of technologies (hydro, nuclear, thermal etc.) and applied consistently for all companies. This is a more stable measure which therefore gives a more balanced idea of return evolution over time.

Furthermore, the depreciation charge has decreased from JPY 415 billion in 1995/96 to JPY 332 billion in 2024/25, whereas gross depreciable tangible assets have increased from JPY 11.2 trillion to JPY 16.9 trillion during the same period, implying a significant distortion between assets and respective depreciation charges.

It is worth noting that the company depreciated assets using the declining-balance method until 2018/19. However, in 2019/20, the company adopted the straight-line depreciation method, resulting in a significant increase in accounting depreciation life from 46 to 55 years.

The table below gives a typology of economic lives of tangible assets estimated by CROCI team for each industry and asset category

Typology of Economic Lives		
Type of business	Sectors	Economic Lives
Technology	Services	4 to 7 years
Assembling	Automotive, Engineering	9 to 12 years
Light Transformation	Pharmaceuticals, Food	10 to 15 years
Heavy Transformation	Steel, Pulp & Paper, Breweries	17 to 25 years
Real Estate-Based *	Hotels, Retail, Restaurants	10 to 30 years
Infrastructure	Utilities	30 to 40 years

* The large distribution of economic lives comes from the varying proportion of lease in these businesses

Linear versus Non-Linear Depreciation

Accountants depreciate assets in a linear fashion, which means that in order to represent obsolescence they subtract equal amounts of capital from the gross level. Economically, however, assets must be depreciated more slowly in the earlier years of their life (assuming no technological progress).

This is made evident by representing assets as the present value of a flow of income, and depreciation, therefore, as the loss of one year of income through obsolescence. The following example illustrates this.

An asset generates ten years of constant income of \$15. Discounted at 8%, the present value of this stream of income is approximately \$100. One year later, only nine years of income are discounted at 8%; the present value is now \$93.5. The loss of the last year's income is worth \$6.5, not \$10, as straight-line depreciation suggests. \$6.5 represents the economic depreciation of this asset.

To be complete, here are two further thoughts.

- Non-linear depreciation makes accelerated depreciation, which depreciates more as assets are young, an economic nonsense, unless it is meant to register high technological progress. In this case, assets have indeed to be written down more quickly while they are young.
- Metrics applying linear depreciation are in danger of misrepresenting the value of net assets, and therefore misjudging potential pricing

anomalies. But this is, unfortunately, not true in all cases. Our suspicion is that, on more than one occasion, two wrongs have ended up making a right, and linear depreciation will be the best synthesis of two contradictory trends; slow and accelerating depreciation to reflect economic decay, and fast and decelerating depreciation to reflect technological progress.

CROCI, which is calculated as the discount rate equalizing cash flows and the inflation-adjusted value of gross assets, is therefore based on economically-adjusted version of linear depreciation.

What About Non-Depreciable Assets?

Above we have dealt at length with depreciable assets. Most—but not all—assets become obsolete with age. There are some that can retain (sometimes considerably increase) their value without being 'maintained'; that is, without additional investment through time. In a finite life model, such as CROCI, those assets that don't die will be recouped by investors at the end of the life of the depreciable assets. We thus add them to the last cash flow. We have identified three types of non depreciable: land, net working capital and goodwill. While the first two are self-explanatory, goodwill requires further explanation.

Goodwill

When an acquirer agrees to pay more than the book value of an asset, the difference is generically called "goodwill". But this amount can represent two very different assets. It can either pay for and reveal invisible capital (i.e. intangible assets not booked by the acquired company - see adjustment 3) or pay for a strategic entrance ticket, call it "market share", with a specific value for the acquirer. In practice, goodwill is a mixture of both.

Deciding whether goodwill is a depreciable or non-depreciable item is of considerable importance for the calculation of CROCI. To the extent that accounting goodwill represents a stock of invisible intangible cash-flow generative assets attached to the acquired company, it must be depreciated according to its economic life. Only beyond this amount does goodwill become a non depreciable asset.

We believe that in general companies can only be compared at an operating level. Since we already capture intangible assets created through acquisition,

we prefer to look at returns excluding the 'super' goodwill—the amount paid over the true (not accounting) asset base.

In any case, operating returns compared to EV/NCI based on operating assets in aggregate tend to result in a higher correlation. We do not find this surprising given that investors clearly realise that managements cannot influence the level of return generated by non-operating assets (i.e. goodwill) and therefore focus on valuing those assets over which they do wield influence. Thus the vast majority of our CROCI analysis focuses on ex-goodwill measures; and the CROCI strategies are all run off Economic PE excluding goodwill.

5. Adjusting for Growth

At this stage of the CROCI model, investors are equipped with:

- *An inflation-adjusted measure of return (CROCI) on economic capital*
- *An asset multiple (EV-to-NCI) which give the price that investors are willing to pay to own one unit of a company's assets.*

Even without too much deep thought, there clearly ought to be some sort of relationship between the two. An asset that can return, say, 6% in real terms should be worth less than an asset that can return twice as much. *The complete function of this relationship is the mathematical description of the stock market.* Alas, it is a very complex function, and one that investors and strategists can only approximate, because it is not linear and depends on many rather than just one variable, including:

- 1- the growth rate of the asset base.
- 2- the period during which this growth rate can be sustained,
- 3- the rate of normalization of growth (to, ultimately, 0%)
- 4- the period during which CROCI can a- expand or b- stay above the cost of capital
- 5- the 'fade' rate, or the rate at which competitive forces drag returns down to the cost of capital
- 6- the long run return of equity assets

Capital invested either grows or shrinks

The starting principle is simple enough, though:

A steady state company, with no growth in capital invested, should have an EV-to-NCI ratio equal to its CROCI-to-Cost of Capital (COC) ratio. Investors could think of this relationship in the terms of the fixed interest market. A fully paid bond with a 12% coupon will trade at 2x par if very long interest rates are 6%.

However, absolutely static companies, even in real terms, are more than rare; companies either grow or retire assets. **This movement in capital invested will change the relationship between the two ratios.** If a company generates returns that are 50% of the cost of capital and grows its capital base with similar returns, its enterprise value will be 50% of its net capital invested **plus the discounted amount of value-destruction generated by the additional capital.** Conversely, a growing, value-creating company will trade at an enterprise value multiple of net capital invested in line with its CROCI-to-COC ratio, **plus** the discounted amount of additional value generated by the extra capital. Furthermore, volatility at the high end of the CROCI scale is higher because the bigger the gap between the cost of capital and return is, the more sensitive valuation becomes to the growth rate.

Figure below shows the EV/ NCI and CROCI relationship for 2025, for approximately 740 companies. As the return on capital, on the horizontal axis, goes higher, investors seem to become irrational, and price companies with similar returns on a large spread of valuation, ranging from 0.3 to 50 times net capital invested.

EV / NCI and CROCI

Source: Company Data, DWS CROCI. Data for 2025 and is as on Dec 2025

Of course, investors are not irrational. What we are capturing here is the fact that some high return companies tend to grow more quickly than the rest of the market, and the higher the return, the more likely it is that the distribution of growth will be uneven.

By systematically defining net assets as the economic capital (including intangible assets etc. defined in a similar way across the board), the CROCI metric will go some way towards eliminating some of the apparent disparities in valuation in accounting metrics as shown in figure below. What will remain is the **genuine difference** that investors ought to make between a 10% growth company and a 5% growth company.

P/BV and ROE

Source: Company Data, DWS CROCI. Data for 2025 and is as on Dec 2025

The Competitive Advantage Period

Although an analysis of the expected growth rate in capital will go a long way in explaining valuation discrepancies of seemingly similar businesses, it is not the only variable. The market is also likely to take a view on the Competitive Advantage Period (CAP), which in financial speak is the period during which the company can sustain a CROCI above the cost of capital. Michael Porter has explained some time ago⁵ how the return on capital of industries eventually converges towards the cost of capital. The same applies to individual companies, albeit in a more random way. The sustainability of CROCI and the rate at which competitive forces will ultimately drag it to the cost of capital ('the fade rate') also need to be assessed by investors.

It is possible to measure, historically, the rate of fade of businesses and companies starting to lose their competitive advantage, i.e. accepting a lower marginal return on capital than their average aggregated CROCI. These measures are precious indications of the competitive forces at work and enable investors to estimate an average medium-term return on asset. As a rule of thumb, a growth company which is entering its first phase of deceleration may see its return on capital falling by 10% per annum.

⁵ Porter, M.E. (1980). *Competitive Strategy: Techniques for Analyzing Industries and Competitors*. The Free Press

Fading returns are not necessarily the sign of a poor business, far from it. There is a tradeoff between the growth rate that the management wishes to achieve and the return that it sees acceptable. The following charts show the CROCI and the asset base of SAP, a European Software company. The management of this company was willing to accept a continuous fall in returns on capital (from 36% to 20%) in exchange for a (8% per annum on average) growth in assets between 2011-22. The combination of the two yielded rising economic earnings till 2020.

SAP

Source: Company Data, DWS CROCI. Data as on 17 June 2026

The reverse DCF model

In our view, the most practical way to analyse 1- the implied growth and 2- the implied CROCI competitive advantage period is to build a reverse Discounted Cash Flow (DCF) model. A classic DCF model will take a view on free cash flow and, discounting it back at a given cost of capital, will find an asset value. A reverse DCF model will not take a view at all. It will simply start from the enterprise value and find a cash flow stream whose net present value is exactly... that EV, or the price that the market puts on the assets in question.

In order to get to a result that can be expressed in terms of CROCI and growth in capital, free cash flow has to be expressed as gross cash flow (CROCI % assets) minus investment (growth in assets). Also, this DCF model does not tolerate a terminal value, and can only work as an 'infinite' model (in practice, two hundred years does the trick). The only assumption is that ultimately, CROCI = COC and that growth in capital invested tends to zero. The rate at which this 'decay' occurs, called the fade rate in valuation jargon, is the most accurate insight that an investor can get on the CAP priced by the market.

If you doubt that investors are conscious of—let alone willing to price! —a Competitive Advantage Period, consider the following example. In mid 2001, the global pharmaceutical sector was trading on an EV-to-NCI ratio of 4.3, with CROCI of 15%. In order to justify this valuation (bearing in mind that ultimately, we have to assume that the CROCI level will fade to the cost of capital), we have to assume that CROCI will remain more or less constant for another 10 years. Interestingly, the latter figure was not far from the remaining life of the average product pipeline of the global majors. When you consider the number of adjustments that we have inflicted to the financial data (mainly inflation and a gigantic write back of intangible assets representing the R&D and marketing expenses), it is remarkable that we find such a meaningful figure. Indeed, the CAP is priced in the equity market, and extracting it from the value of the assets brings insight in the investment process, we think.

II. The Cost of Capital

Hitherto, the concept of the cost of capital has been omnipresent, yet undefined. We are trying to stay clear of the vast theoretical debate around the cost of capital, to apply practical and simple rules designed to value equities. The traditional measure of the cost of capital, known as the total return theory, is of limited interest to value equities at a given point, in our opinion. This is because it purports to calculate, by computing the total return of a stock market over a very long period, an average historical cost of capital. Even if data existed to calculate such a number for markets other than the US market, knowing the average historical cost of capital is of little help to assess the value of equities today. For sure, evidence points to a strong mean reversion around this average number but recognising this is precisely acknowledging that at a given point, the cost of capital can be substantially above, or below, the average. It is, however, a useful reference point for looking at a discount rate in a historical context.

The **spot** cost of capital is more of a practical item for equity investors. We define it as the discount rate which, at the market level, equalises expected future cash flows and the market value of assets, or enterprise value. By definition, this number **is the expected return of equity investors in aggregate**, aka the 'cost of capital'. We use this number for two purposes; calculating a risk premium and defining the hurdle rate above which companies can create value.

1. Calculating an implied risk premium

In order to calculate the IRR of the market, investors need to model cash flows, and therefore make some assumptions about the shape of the cash flow cycle and the long run real return of equity investments. Historical CROCI data shows the cyclical amplitude of market CROCI to be at least 150 basis points. As for the long run real return of equity assets, various studies, including our own, point to a 5.5% to 6% range. If markets are high (the EV is high), the required discount rate will be low. Investors will be willing to commit capital to the equity market, without demanding a large premium over the risk-free rate. The last part, i.e. 1996-2000 of the 8 year bull market that started in 1992 is a very good illustration of this point.

We isolate the expected equity return from the cost of capital by deducting the debt element with reference to the corporate bond spread over risk free assets.

The second stage is to extract the risk premium from the equity component of the discount rate and in order to do that, one needs to take a view on a likely real risk free rate. Unfortunately, quoted financial instruments which could give such a number are rare, and when they exist, tend to be very illiquid and as such unreliable. We prefer to use a number of long term studies that indicate a strong mean reversion around 3% for risk free securities. If the expected return of equities were 5%, we would calculate the equity premium to be $5 - 3 = 2\%$. Sadly, we are lacking a meaningful historical depth to judge if this method is helpful to investors. Hitherto, the decade and a half of data that we have suggests that the global equity premium ranges from 1% to 3%, a smaller number than most investors would have guessed. Those who can bear with us for another two or three decades may have more precise information!

2. Expected return as a hurdle rate

To benchmark individual company CROCI, we used to calculate country costs of capital, which varied slightly according to inflation expectations. With the globalisation of markets, it soon became apparent that for the largest companies in the world, there was a universal cost of capital, itself probably derived from a dollar-based cost of capital, US investors being the single largest pool of equity investors in the world. As a result, we use a **global cost of capital** to determine if a company is value creative or not. Nowhere more than in Asia, including Japan can we see that regional considerations are being superseded by global trends, at least as far as equities attracting international investors are concerned. With the exception of South Korea only, we obtain the same explanatory power as we do for US or European equities using our global cost of capital.

What about individual risk premia? Whilst we believe that there is probably some mileage to gain by differentiating the cost of capital by risk profile, we are struggling to find an easy way around this difficult subject. Being distrustful of backward looking measures applied to forward looking expectations, we are not huge fans of the 'beta' route. For us, the only way that one could conceive differentiated risk premia would be by calculating individual IRRs. The problem with this suggestion is that one needs to know for certain the future cash flow profile (otherwise, we have two unknowns for one equation), in other words the competitive advantage period!

Introduction to CROCI Approach for Banks

CROCI is essentially a valuation approach based on the due diligence of company accounts. An understanding of risks and sources of return is necessary for us to add a company to CROCI coverage. So, whilst we have been analysing the accounts of financial companies since 2007, uncertainties around the structural and regulatory changes to the industry and their reflection of its economic reality earlier prevented their inclusion in our full investible coverage.

The tightening of regulation following the financial crisis, however, has helped to clarify the financial statements of US banks. New standards have curtailed management's free rein to determine asset risk profiles and levels of required capital have increased. Some jurisdictions, e.g. Australia, even have regulations tougher than international standards.

The move to the expected credit loss model, regular stress testing, higher capital requirements for systemically important banks, etc. have been crucial in strengthening the banking system. However, in the U.S. there has been some loosening of regulatory standards for smaller banks in the past few years. The option given to smaller banks to ignore accumulated other comprehensive income (AOCI), especially unrealized losses on their bond portfolios, in capital calculations was among the main causes of the crisis in U.S. regional banking space in 2023.

A sudden increase in the Fed's policy rate after the pandemic led to large losses unrealized in these banks' bond portfolios but as depositors started looking for higher yields elsewhere, a sale of these bonds to handle deposit pressure resulted in losses being realized and capital being wiped-off. CROCI, however, does not give any bank the option to ignore AOCI and hence our estimated CET1 capital levels indicated this risk clearly. The episode also highlights the importance of harmonizing global capital calculations while evaluating the risks of the banking sector.

CROCI and Banks

It is often assumed that banks are too difficult to do on CROCI, or that the CROCI model doesn't work for banks. Neither is really true. Banks are in many ways easier to analyse than non-financial companies. The asset side of their

balance sheet is composed of monetary assets which do not need complex inflation adjustment, or the capitalization of intangible assets. In fact, the model "works" just as well for banks as it does for any other operating asset.

The difficulty, however, is the calculation of the relevant market value. An enterprise value that included all debt would be of limited interest, considering that a bank's balance sheet can be leveraged up to 12x, against 1x on average, for non-financial companies. As a result, the slightest error in the assessment of banks' total liabilities would have disproportionate consequences for the conclusions on valuation. It is much more appropriate for a banks model to be expressed in terms of equity and net assets. So, the traditional price-to-book and RoE approach—in other words the normal PE ratio—is more meaningful for a bank than for a non-financial company.

The non-applicability of the industrials approach

CROCI challenges traditional accounting conventions and lays great emphasis on cash-flow-based analysis. For banks, this is not very relevant because, for them, cash is an operating asset. Similarly, borrowing and lending' is tantamount to 'manufacturing and selling' at non-financial companies. Further, Fixed Assets represent only 1% (see table on Page 1041) of a bank's total assets; consequently, depreciation policies have very little impact on bank profitability.

Banks are highly regulated entities and their leverage levels, though much higher than non-financials, are restricted by regulations. These regulations vary across jurisdictions. Hence, bringing banks to a common standard and determining their genuine capital-adjusted performance requires a different approach.

Banks bear a higher cost of capital than non-financials

Using a traditional price-to-book and RoE approach is severely flawed if investors want to know whether BNP Paribas is better value than Saint-Gobain, or if Wells Fargo is more expensive than Coca-Cola. This may not be of huge interest for those who want to keep a small tracking error, for investors who are benchmark huggers. But for value investors who seek diversification and want

to position their portfolio where value is, irrespective of market cap weights, the PE ratio is of much less use.

The reason is that the level of the PE gives an idea of value (an imperfect one with accounting data, but an idea nonetheless) and a measure of expected return, i.e. of risk premium. Banks are on a lower PE ratio than non-financial companies, on average, not because they are better value in an absolute sense, but because they are more risky, i.e. priced with a higher risk premium than the rest of the market. In this respect, it makes little sense that index providers fill up their value indices with bank shares (with a weight of typically more than 30%), without adjusting for their higher risk. Their low multiple is treated as offering value without compensating for the increased risk.

Need for Continued Evolution of Banks Model

The banking sector is heavily regulated and strongly correlated with the economy, so tends to witness regular intervention by regulatory authorities. A non-financial company can certainly expect changes to its business environment over the cycle, but a bank can be subjected to a whole raft of regulations.

The Basel rules are a good illustration of this. Basel I was criticized for being less sensitive to the risks faced by banks. This led to Basel II, which allowed banks to use their own internal ratings-based models. However, regulators realized that capital requirements calculated using internal models were lower than those given by standardized models in a large majority of cases. As a consequence, the Basel committee is now proposing regulations that would restrict the use of internal models. Thus regulations seem to have come full circle. Long-term investors need to account for the fact that bank regulations are rarely static and can be cyclical, just like business cycles.

Also, regulations vary across jurisdictions and, despite concerted efforts by authorities to harmonise them, it is unlikely that these variations will converge any time soon. A case in point is capital floors—in Europe, some countries strongly oppose their introduction whereas the US is in favour of them. Since regional differences are a consequence of differences in economic, monetary and credit cycles, these factors are unlikely to go away.

In the end, value investors need to continuously monitor and account for these variations in their analysis of the sector. This is in keeping with our differentiated CROCI approach for analyzing banks, in which we meticulously revise our models to adjust for national variations whilst also ensuring that valuations reflect economic reality as far as possible.

The Need for a Different Valuation Approach for Banks

A bank's business is very different from a non-financial company's business in nearly all aspects. Below are the major differences between the balance sheet compositions of a bank and a non-financial company.

	Banks	Non-Financials
Total Assets	100	100
- Cash and Other Securities	41	10
- Trading & Derivative Assets	11	4
- Net Loans	39	-
- Net Goodwill and Intangibles	2	25
- Tangible Fixed Assets	1	37
- Other Assets	7	24
Total Liabilities & Shareholder's Funds	100	100
- ST Debt and Trading Liabilities	12	14
- Deposits	63	4
- Debt Securities	10	35
- Other Liabilities	6	9
- Share Holders Funds & Minorities	9	38
Market Capitalization	14	245

The majority of the assets & liabilities on banks' balance sheets are monetary items carried at market value. Non-financials tend to carry them at historical cost, so an inflation adjustment is necessary to bring them into current cost.

In aggregate, Fixed Assets represent only 1% of a bank's total assets. As a result, differences in depreciation policies have very little impact on bank profitability, unlike for non-financial companies

Banks have much higher financial leverage than non-financial companies. Heavy regulation means that they are also required to maintain a minimum level of capital.

Source: DWS CROCI. Aggregated data of companies in CROCI coverage. The data is rebased to 100 and is as available as on 17th June 2026
Sample Size for Financials: 20 Banks (US CROCI Coverage); Non-Financials: 346 Companies (US CROCI Coverage).

Almost all operating assets of banks are monetary in nature for which depreciation-related adjustments are not relevant. Nor is 'useful life' a relevant concept for these assets. Cash serves in a liquidity and debt management role for non-financial companies but is more of an operating asset for a bank.

Non-financials tend to carry assets at historical cost, so an inflation adjustment is necessary to bring them to current cost. In general, this is not necessary for a bank's monetary assets, as they are already in current cost.

On the liability side of the balance sheet, most of the non-equity portions are composed of monetary liabilities. This is true not just for deposits, which form a

large part of a bank's liabilities, but also bonds. In many cases, a bank issues bonds not to fund its capital expenditure but to fund its loan growth, making these bonds effectively operating liabilities rather than invested capital.

Similarly, borrowing and lending' is equivalent to 'manufacturing and selling' at non-financial companies. This also explains why banks are highly leveraged entities whose equity forms a much lower proportion of their balance sheets. Heavy regulation means that they are also required to maintain a minimum level of capital, though.

Coming to the income statements of banks, non-cash items make up a very small proportion of their income or expenses. In addition, whereas leverage-related expenses have a distorting impact on the operating metrics of non-financial firms, for banks such expenses—such as interest payments for deposits or bonds issued—are legitimate operating expenses which require no adjustment.

Another major difference between banks and non-banks relates to their cost of capital. Given their high leverage and systemic nature, banks tend to be more sensitive to macroeconomic changes and have shorter business cycles than non-financial companies. Hence, investors have historically expected higher returns from banks and consequently banks' cost of capital has been observed to be higher than that of non-financial companies.

Keeping in mind the need for changes to our usual CROCI analysis, we use a differentiated valuation framework for banks. We highlight the main elements of this framework in the following paragraphs.

Enterprise Value is largely composed of market capitalisation

Enterprise Value (EV) measures what the market believes a company's ongoing operations are worth. It represents the value of the company's business as a whole—not only from the perspective of equity shareholders but also from the perspective of debt holders and all other capital providers. In case of banks, market capitalization, i.e. the market value of equity, is a very large component of enterprise value. Additionally, we consider the value of Tier 1 debt as part of EV. Unrecognised gains from non-financial holdings and other strategic investments as well as Deferred Tax Assets from Operating Loss Carry-forwards reduce the EV.

Adjusted Tier 1 Capital instead of NCI

The bank's version of NCI is Adjusted Tier 1 Capital. This is the regulatory capital as reported by the company and normalised for differences across regulators to allow comparison between different countries on a common standard. We evaluate returns at the Tier 1 Capital level instead of just equity to preserve similarity to our treatment of non-financial companies, whose returns are measured on a de-levered basis. Due to the highly regulated nature of the banking industry, the Tier 1 capital of a bank tends to be a good reflection of its invested capital.

Inflation Adjusted Earnings

Given the largely monetary nature of a bank's asset base, inflation adjustment is not directly applicable to the assets. However, we do adjust banks' earnings for inflation in order to normalize their cash flows in an inflationary environment. Hence, we apply the GDP deflator to a bank's Adjusted Tier 1 Capital and deduct it from earnings to arrive at inflation adjusted earnings.

For banks there is no need to adjust for depreciation and other non-cash items, as in the case of non-financials, because these are small in relation to the total earnings. In other words, there is less of a need for investors to use adjusted cash flow models for banks.

The CROCI metric for banks is called Inflation Adjusted Return on Capital, the ratio of Earnings to Adjusted Tier 1 Capital.

Adjusting for Exceptionals

We adjust for exceptional items on a systematic and comparable basis, removing all the noise created by reporting. For example, we do not treat litigation charges as exceptional (even if the amount is very significant). We believe that the strict regulatory framework of the business demands the entire sector be discounted for litigation costs.

Main Regulatory Adjustments

We normalize reported regulatory capital to make it comparable across regions on a consistent and economic basis. A few examples are listed below.

i) Significant Investments

Significant investments in banking, financial and insurance entities are deducted from CET 1 capital under Basel III. However, EV is computed for the entity as a whole and income from associates form a part of the inflation adjusted earnings in our model. Thus to make Adj. Tier 1 Capital consistent with these, we add back such significant investments (that are deducted from CET 1 capital) to our Adjusted Tier 1 Capital.

ii) AOCI opt-out in case of small US Banks

US banks that are not following an advanced approach are allowed a one-time permanent election in the first reporting period under Basel III to exclude AOCI (Accumulated Other Comprehensive Income) from the

calculation of regulatory capital. In case of such opt outs, we add back AOCI related gains or losses to Adjusted Tier 1 Capital.

iii) Adjusting for regional differences

In the case of Australian banks, APRA does not have threshold deductions as Basel III does, and the entire amount of Deferred Tax Assets is deducted. There are also deductions relating to deferred fee revenue, capitalized expenditure etc. that are over and above the deductions to be made under Basel III. To maintain uniformity in Adjusted Tier 1 capital with other banks, we add back these country specific deductions.

As a result of these adjustments, the Inflation-Adjusted ROC of banks, as calculated using the CROCI approach, is quite different from the accounting Return on Equity. The impact of the various CROCI adjustments is demonstrated below. For US banks in 2025, for example, inflation adjustment, and the addition of AT1 to the capital base were responsible for the biggest differences between Inflation-Adjusted ROC and accounting ROE.

Effect of adjustments for US Banks: ROE to inflation-adj. ROC (2025)

Differential Cost of Capital (COC)

Financial companies generally trade at a lower P/E ratio than non-financial companies. This differential in valuation is not necessarily indicative of value but often reflects the higher risk of financial companies. In order for financial stocks to be rendered comparable with non-financials, it is crucial to adjust for this difference in risk before selecting stocks on a systematic basis.

The earnings yield (the reciprocal of the P/E ratio) of financials is structurally higher than that of non-financial companies. For example, since 1991 the S&P 500 Financials index average yield has been 158 bps higher than that of the broader S&P 500 index.

This structurally higher yield represents the premium that investors demand for accepting the higher risk in the sector, principally in the form of higher leverage. Because of this increased risk, investors in banks tend to require a higher return for holding bank equities than they do for non-financial equities.

To make valuation comparable across CROCI's entire coverage, financial company P/E ratios are adjusted by the ratio of long-term COC of financials (8.1%) to that of non-financial companies (4.6%).

$\text{COC Adjusted P/E} = \text{Adjusted P/E} * (\text{Cost of Capital for Financials} / \text{Cost of Capital for Industrials})$
